EndoSim Part A: hormones and feedback

Group worksheet · 40 points foxworthywa.github.io/neuronsim/endo.html

Names: _____

The idea in one line: a gland's hormone travels to every cell, acts only where there is a receptor, and holds back the glands that told it to work. Read the levels above and below a problem, and you can find the broken link.

How to use this sheet. Part A before you open the sim. In Part B the numbers match the circles across the top of the sim: when a box names a scene, stop there and answer together. Write predictions BEFORE you press the run button. **TALK FIRST** means every person says their answer out loud before anyone writes: disagree first, then write what you agreed. Part C is answered after the sim, in full sentences, using your own numbers. One sheet per group.

A · Before you open the sim

from the textbook or lecture, and what you already know (4 points)

Draw the thyroid axis: boxes for the hypothalamus, the anterior pituitary, the thyroid and the body's cells. Name the hormone on each arrow. Then draw the feedback arrow(s) from thyroid hormone, marked with a "−", to wherever you think they go. (2 points)

your diagram

TALK FIRST TSH is a protein (water-soluble). T4 is made from the amino acid tyrosine plus iodine, and is fat-soluble. Predict, for each hormone: is its receptor on the cell surface or inside the cell? Which would you expect to last longer in the blood? Why? (2 points)

B · Working through the sim

keyed to the scene numbers (14 points)

1 A message for every cell · *on screen: "Which cells respond?"* (1 point)

TSH reached _____ of the four cells. _____ of them responded. What decides whether a cell responds to a hormone? Half-life of TSH _____; of T4 _____.

2 You are the pituitary · *on screen: "Keep free T4 in range for 30 days"* (2 points)

Our best time with free T4 in range: _____ %. The automatic pituitary: _____ %.

TALK FIRST What made it hard for you? What does the real pituitary sense that lets it do better?

3 Pull the levers · *on screen: "Experiments 1–3"* (3 points)

Before each run, write your group's prediction (↑, ↓ or –). After the run, write what happened. Circle any prediction that was wrong.

Experiment	TRH predicted	TRH observed	TSH predicted	TSH observed	Free T4 predicted	Free T4 observed

1. Thyroid removed						
2. T4 tablets, healthy person						
3. Pituitary blocked						

Our rule, in our own words: when one level of the chain fails, the hormone it makes _____, and the hormone above it _____, because _____.

4 Glands grow on command · *on screen: "No iodine · T4 tablets for 6 months · Maria starts levothyroxine"* (3 points)

Iodine-poor diet, 6 months: thyroid _____ → _____ g; TSH _____ mIU/L; free T4 _____ ng/dL.

T4 tablets, 6 months: thyroid _____ → _____ g; the thyroid's own T4 output _____ → _____ µg/day.

Maria on levothyroxine: TSH at start _____, week 1 _____, week 6 _____ mIU/L; free T4 at start _____, week 1 _____ ng/dL.

TALK FIRST In one sentence, using the word trophic: why did the thyroid grow in one experiment and shrink in the other?

5 A second axis, a daily rhythm · *on screen: "When was the blood drawn? · Stress"* (2 points)

Cortisol at 8 am _____ µg/dL; at midnight _____ µg/dL. With 6 hours of stress, cortisol at 6 pm _____ (without stress _____).

TALK FIRST A nurse draws blood for cortisol at 9 pm and the result is 4 µg/dL. Is that low? What would you want to know before deciding?

6 The steroid taper · *on screen: "Eight weeks of prednisone · Daniel stops all at once · A taper"* (2 points)

Adrenal size at the start _____ g; after 8 weeks of prednisone _____ g.

Stopped abruptly: lowest daily cortisol effect _____ µg/dL, _____ crisis days. Tapered: lowest _____ µg/dL, _____ crisis days.

7 Tests that push the loop · *on screen: "A suppression test · A stimulation test · Patients 1 and 2"* (1 point)

Person	8 am cortisol	8 am ACTH	Test and result	Where is the problem?
Healthy			Dexamethasone 1 mg → 8 am cortisol _____	none
Healthy			Cosyntropin → _____ to _____ µg/dL	none
Patient 1, Ms. Rivera				
Patient 2, Mr. Tran				

Paste the results text from the last screen of the sim on the back of this sheet (or attach it), and write your completion code here: _____

C · After the sim full sentences, your own numbers; explain why, not just what (18 points)

1. Maria's TSH. Maria's thyroid is failing, so why is her TSH high? Use the term negative feedback. Then predict what her TSH and free T4 would have been if the problem had been in her pituitary instead, and explain why. (4 points)

2. Why six weeks? Using your week-1 and week-6 numbers for Maria, explain why her doctor rechecks TSH after six weeks rather than one. Include the half-life of T4 and what happened to TSH. What could go wrong if the dose were changed at week 1? (4 points)

TALK FIRST 3. Maria's sister. Her sister wants to take thyroid pills to lose weight. Predict what would happen to her sister's TSH, her thyroid's own T4 output and the size of her thyroid. What might happen if she then stopped suddenly? Use your scene 3 and 4 results, and what you saw with Daniel. (3 points)

4. Daniel's crisis. Explain, as a chain of at least four causes and effects, why stopping prednisone suddenly made Daniel ill. Then explain why the taper prevented it, using your numbers. Finish with one thing a nurse should teach a patient starting a long course of prednisone. (4 points)

TALK FIRST 5. Transfer: Graves' disease. In Graves' disease the immune system makes an antibody that switches on the TSH receptor, like TSH does, but nothing holds it back. Predict this patient's TSH, free T4 and thyroid size, and explain why TSH is low even though the thyroid is overactive. A radioactive iodine uptake scan measures how hard the thyroid is working. How would it tell Graves' disease apart from someone secretly taking thyroid pills? (3 points)
